I. INTRODUCTION

In 1941, Rarita and Schwinger proposed a quantum-field theory for particles with an arbitrary half-integral spin \( s \) [1]. Today, 70 years later, this theory is commonly used to describe phenomena that involve relativistic high-spin fermions. We address the issue of consistent interactions for off-shell fermion fields of arbitrary spin. These interactions play a crucial role in the quantum hadrodynamical description of high-spin baryon resonances in hadronic processes. The Rarita-Schwinger (R-S) description of high-spin fermion fields involves unphysical degrees of freedom associated with their lower-spin content. The invariance condition of the interaction under the unconstrained R-S gauge removes the lower-spin content of the fermion propagator and leads to a consistent description of the interaction. We develop the most general consistent interaction structure for high-spin fermions. We find that the power of the momentum dependence of a consistent interaction rises with the spin of the fermion field. This leads to unphysical structures in the energy dependence of the computed tree-level cross sections when the short-distance physics is cut off with standard hadronic form factors. A spin-dependent hadronic form factor is proposed that suppresses the unphysical artifacts.

The notation \((1b)\) by construction, R-S fields have redundant degrees of freedom \((\text{dof})\), which are associated with unphysical lower-spin components. These enter the interaction if not eliminated outright. The invariance condition of the interaction under the unconstrained R-S gauge removes the lower-spin content of the fermion propagator and leads to a consistent description of the interaction. We develop the most general consistent interaction structure for high-spin fermions. We find that the power of the momentum dependence of a consistent interaction rises with the spin of the fermion field. This leads to unphysical structures in the energy dependence of the computed tree-level cross sections when the short-distance physics is cut off with standard hadronic form factors. A spin-dependent hadronic form factor is proposed that suppresses the unphysical artifacts.

II. CONSISTENT INTERACTIONS

A. The massive spin-5/2 field

1. Gauge invariance as a requirement for a consistent interaction theory

A general interaction theory for a massive off-shell spin-5/2 field \( \psi_{\mu 1} \) and an on-shell source \( J_{\mu 1} \) can be constructed from...
a Lagrangian of the type,
\[ \mathcal{L}_I = \bar{\psi}_{\mu
u} J^{\mu\nu} + \bar{J}_{\mu\nu} \psi^{\mu\nu}, \]
where the subscript \( I \) stands for interaction. To obtain a consistent spin-5/2 interaction theory, \( \mathcal{L}_I \) has to be constructed in such a way that only the physical \( P^{5/2}_{\mu\nu\lambda\rho}(\partial) \psi^{\lambda\rho} \) component of \( \psi_{\mu\nu} \) mediates the interaction, i.e.,
\[ \Gamma^{5/2}_{\mu\nu}(\{ p_{\mu\nu} \}) P_{\mu\nu\lambda\rho}(p) \Gamma^{\lambda\rho}_{\mu\nu}(\{ p_{\mu\nu} \}) = \Gamma^{5/2}_{\mu\nu}(\{ p_{\mu\nu} \}) \frac{\dot{p}}{p^2} + m P^{5/2}_{\mu\nu\lambda\rho}(p) \Gamma^{\lambda\rho}_{\mu\nu}(\{ p_{\mu\nu} \}), \]
with \( m \) as the mass of \( \psi_{\mu\nu} \), \( \Gamma^{5/2}_{\mu\nu}(\{ p_{\mu\nu} \}) \) as the initial-final interaction vertex, which is derived from the source \( J^{\mu\nu}_{p_{\mu\nu}} \), \( P_{\mu\nu\lambda\rho}(p) \) as the spin-5/2 propagator, and \( P^{5/2}_{\mu\nu\lambda\rho}(p) \) as the spin-5/2 projection operator. Furthermore, \( p \) represents the four-momentum of \( \psi_{\mu\nu} \), and \( \{ p_{\mu\nu} \} \) denotes the collection of four-momenta of the fields that are contained in \( J^{\mu\nu}_{p_{\mu\nu}} \).

The explicit expressions for the spin-5/2 projection operator and the spin-3/2 and spin-1/2 projection operators, which project the field \( \psi_{\mu\nu} \) onto its unphysical spin-3/2 and spin-1/2 components, are given in Appendix A.

The propagator \( P_{\mu\nu\lambda\rho}(p) \) can be projected onto the spin-5/2, the spin-3/2, and the spin-1/2 projection operators, which span the complete spin-5/2 space in the R-S representation. As seen from Eqs. (A1)–(A3), the spin-projection operators contain terms that are proportional to \( p^2 \) and \( p^{-4} \). However, to describe a massive off-shell spin-5/2 field in a physically meaningful way, \( P_{\mu\nu\lambda\rho}(p) \) has to be regular for \( p^2 \to 0 \). So, in the expression for \( P_{\mu\nu\lambda\rho}(p) \), the singular terms, which stem from the spin-projection operators, have to cancel each other out.

In a consistent spin-5/2 interaction, only the physical spin-5/2 component of \( P_{\mu\nu\lambda\rho}(p) \) remains, as expressed through Eq. (4). Since the left-hand side of Eq. (4) is regular for \( p^2 \to 0 \), the right-hand side of this equation has to be regular for \( p^2 \to 0 \) as well. So, for Eq. (4) to hold, the singular terms of the spin-5/2 projection operator have to be removed by the interaction vertices \( \Gamma^{5/2}_{\mu\nu}(\{ p_{\mu\nu} \}) \). This implies that the interaction vertices cannot be completely arbitrary. Instead, they have to be constrained by a certain local symmetry. This local symmetry can readily be found. Indeed, all of the singular terms of \( P^{5/2}_{\mu\nu\lambda\rho}(p) \), at least, are linear in \( p_{\mu\nu}, p_{\nu\lambda}, p_{\lambda\rho}, \) or \( p_{\rho\mu} \). It is straightforward to show that the right-hand side of Eq. (4) is only regular for \( p^2 \to 0 \) when the interaction vertices satisfy the following transversality conditions:
\[ p_{\mu} \Gamma^{\mu\nu}_{I} = 0, \quad p_{\nu} \Gamma^{\mu\nu}_{I} = 0. \]
This requirement is equivalent to the invariance of \( \mathcal{L}_I \) under the unconstrained spin-5/2 R-S (uR-S5/2) gauge,
\[ \psi_{\mu\nu} \to \psi_{\mu\nu} + \frac{i}{2}(\partial_{\mu} \chi_{\nu} + \partial_{\nu} \chi_{\mu}), \]
where \( \chi_{\mu} \) represents an arbitrary space-time-dependent rank-1 tensor-spinor field. The invariance of interaction theories under the uR-S5/2 gauge of Eq. (6) is the required local symmetry that guarantees the consistency of massive off-shell spin-5/2 interactions.

To construct interaction vertices (which are derived from the sources) that satisfy conditions (5) is not a trivial task. However, by using a field construction that is invariant under the uR-S5/2 gauge (6), the problem of finding conserved sources can be circumvented.

2. The gauge-invariant field

Inspired by the gauge-invariant field,
\[ G_{\mu\nu} = i \left( \partial_{\mu} \psi_{\nu} - \partial_{\nu} \psi_{\mu} \right), \]
which was introduced by Pascalutsa in Ref. [5] to set up consistent interaction theories for spin-3/2 particles, a gauge-invariant spin-5/2 field can be constructed. The field \( G_{\mu\nu} \) can be rewritten as
\[ G_{\mu\nu} = i \left( \partial_{\mu} g_{\nu\lambda} - \partial_{\nu} g_{\mu\lambda} \right) \psi^{\lambda} = O^{3/2}_{(\mu,\nu)\lambda}(\partial) \psi^{\lambda}, \]
which reveals the interaction operator \( O^{3/2}_{(\mu,\nu)\lambda}(\partial) = -O^{3/2}_{(\nu,\mu)\lambda}(\partial) \). This operator has the following property:
\[ \partial^{\lambda} O^{3/2}_{(\mu,\nu)\lambda}(\partial) = O^{3/2}_{(\nu,\mu)\lambda}(\partial) \partial^{\lambda} = 0, \]
which ensures the invariance of \( G_{\mu\nu} \) under the uR-S5/2 gauge. The notation \((\mu, \nu, \lambda)\), for the tensor indices of the spin-3/2 interaction operator, is used to separate the actual Lorentz indices of the gauge-invariant field, i.e., \( \mu \) and \( \nu \), from the Lorentz index that is contracted with the spin-3/2 field, i.e., \( \lambda \). The corresponding spin-5/2 interaction operator, i.e., \( O^{5/2}_{(\mu,\nu,\lambda,\rho)\sigma}(\partial) \), is constructed from the direct product of two spin-3/2 interaction operators,
The corresponding gauge-invariant field for the spin-5/2 theory reads
\[ G_{\mu\nu,\lambda\rho} = O^{5/2}_{(\mu\nu,\lambda\rho)\sigma\tau}(\partial)\psi^\sigma^\tau = -\partial_\mu\partial_\nu\psi_{\lambda\rho} - \partial_\lambda\partial_\rho\psi_{\mu\nu} + \frac{1}{2}(\partial_\mu\partial_\nu\psi_{\lambda\rho} + \partial_\lambda\partial_\rho\psi_{\mu\nu} + \partial_\mu\partial_\rho\psi_{\nu\lambda} + \partial_\nu\partial_\lambda\psi_{\mu\rho}), \tag{11} \]
where the symmetry of the spin-5/2 field, i.e., \( \psi_{\mu\nu} = \psi_{\nu\mu} \), has been applied. This field is invariant under the uR-S_{5/2} gauge
\[ \Box G_{\mu\nu,\lambda\rho} = -\partial_\mu\partial_\nu\psi_{\lambda\rho} + \partial_\lambda\partial_\rho\psi_{\mu\nu} + \frac{1}{2}(\partial_\mu\partial_\nu\psi_{\lambda\rho} + \partial_\lambda\partial_\rho\psi_{\mu\nu} + \partial_\mu\partial_\rho\psi_{\nu\lambda} + \partial_\nu\partial_\lambda\psi_{\mu\rho}), \tag{12} \]
The specific definition (10) for the spin-5/2 interaction operator is chosen so as to symmetrize \( G_{\mu\nu,\lambda\rho} \), i.e.,
\[ G_{\mu\nu,\lambda\rho} = G_{\nu\mu,\lambda\rho} = G_{\mu\nu,\rho\lambda} = G_{\nu\mu,\rho\lambda}, \tag{13} \]
An interaction theory constructed from \( G_{\mu\nu,\lambda\rho} \) and a source \( T_{\mu\nu,\lambda\rho} \), i.e.,
\[ \mathcal{L}_I = G_{\mu\nu,\lambda\rho} T^{\mu\nu,\lambda\rho} + \mathcal{T}_{\mu\nu,\lambda\rho} G^{\mu\nu,\lambda\rho}, \tag{14} \]
consequently, generates interaction vertices that obey the transversality conditions of Eq. (5).

3. The propagator and the consistent interaction structure
Apart from the interaction vertices, the Feynman propagator is another key element in the quantum-field theory of an interaction. The Lagrangian \( \mathcal{L}_I \), defined in Eq. (14), gives rise to the following interaction structure:
\[ O^{5/2}_{(\mu\nu,\lambda\rho)\sigma\tau}(\partial)P^{\sigma\tau,\sigma'\tau'}(p)O^{5/2}_{(\mu'\nu',\lambda'\rho')\sigma'\tau'}(p), \tag{15} \]
in the transition amplitude. In Ref. [6], Shklyar et al. derived an explicit form for the spin-5/2 propagator \( P^{\mu\nu,\lambda\rho}(p) \). This propagator form, however, is not suitable for the current analysis because it does not lead to the consistent interaction structure of Eq. (4). In other words, with the propagator of Ref. [6], the imposed condition of invariance of the interaction theory under the uR-S_{5/2} gauge (6) is not sufficient to remove the unphysical interactions from the Feynman amplitude. Indeed, using properties (12) in momentum space and the explicit definitions of the lower-spin projection operators (A2) and (A3), it is easy to show that
\[ O^{5/2}_{(\mu\nu,\lambda\rho)\sigma\tau}(p)P^{3/2,\sigma\tau,\sigma'\tau'}_{ij}(p)O^{5/2}_{(\mu'\nu',\lambda'\rho')\sigma'\tau'}(p) = 0, \quad i,j = 1,2, \quad ij \neq 22, \tag{16} \]
and
\[ O^{5/2}_{(\mu\nu,\lambda\rho)\sigma\tau}(p)P^{3/2,\sigma\tau,\sigma'\tau'}_{kl}(p)O^{5/2}_{(\mu'\nu',\lambda'\rho')\sigma'\tau'}(p) = 0, \quad k,l = 1,2,3, \quad kl \neq 22. \tag{17} \]
This implies that all the lower-spin components of \( \psi_{\mu\nu} \), except for \( P^{1/2,\mu\nu,\lambda\rho}(p)\psi^\lambda^\rho \) and \( P^{3/2,\mu\nu,\lambda\rho}(p)\psi^\lambda^\rho \), decouple from a gauge-invariant spin-5/2 interaction. The propagator from Ref. [6], however, contains these projection operators for arbitrary values of its two free parameters. For a specific choice of one of the parameters, \( P^{3/2,\mu\nu,\lambda\rho}(p) \) can be removed from the propagator. However, this is not the case for the spin-1/2 sector, and the interaction always receives contributions from the propagating \( P^{3/2,\mu\nu,\lambda\rho}(p)\psi^\lambda^\rho \) component. This peculiarity is intimately related to the infamous discontinuity in the R-S description of spin-5/2 fields, which was found by Berends et al. in Ref. [7]: The zero-mass limit of the massive theory does not coincide with the massless theory, which is invariant under the R-S_{5/2} gauge (2). The conclusion is that a gauge-invariant spin-5/2 propagator, i.e., without terms proportional to \( P^{3/2,\mu\nu,\lambda\rho}(p) \) and \( P^{3/2,\mu\nu,\lambda\rho}(p) \), cannot be derived from the massive spin-5/2 theory. It is clear that, to construct a consistent interaction from a gauge-invariant theory, a different approach should be adopted.
The commonly used spin-3/2 propagator reads [8]
\[ P_{\mu\nu}(p) = \frac{p + m}{p^2 - m^2} \left( g_{\mu\nu} - \frac{1}{3} \gamma_\mu \gamma_\nu - \frac{1}{3m} (\gamma_\mu p_\nu - \gamma_\nu p_\mu) - \frac{2}{3m^2} p_\mu p_\nu \right), \tag{18} \]
It is important to note that this propagator results from a massive theory that is invariant under the R-S_{5/2} gauge in the zero-mass limit [5]. The projection operator that projects the spin-3/2 field \( \psi_{\mu\nu} \) onto the physical spin-3/2 component \( P_{\mu\nu}^\lambda(\partial)\psi^\lambda \) is given by [8]
\[ P_{\mu\nu}^\lambda(\partial) = \left( g_{\mu\nu} - \frac{1}{3} \gamma_\mu \gamma_\nu - \frac{p_\mu}{3p^2}(\gamma_\mu p_\nu - \gamma_\nu p_\mu) - \frac{2}{3p^2} p_\mu p_\nu \right), \tag{19} \]
A closer inspection shows that the gauge-invariant spin-3/2 propagator (18) can be obtained from the spin-3/2 projection operator (19) by means of the following substitutions:
\[ p \rightarrow m, \quad p^2 \rightarrow m^2, \tag{20} \]
and subsequently, by multiplying it with \((p - m)^{-1}\). Since \([\partial, \gamma_\mu] \neq 0\), the substitution \( p \rightarrow m \) of Eq. (20) only holds when all the \( p \)'s are moved to the left from the Dirac matrices, which is the case in expression (19). Equivalently, when all the \( p \)'s are moved to the right from the Dirac matrices, the substitution \( p \rightarrow -m \) should be carried out. By applying the prescription of Eq. (20) to the spin-5/2 projection operator (A1), the following expression for the spin-5/2 propagator is
obtained:

\[
P_{\mu \nu; \lambda \rho}(p) = \frac{\phi + m}{p^2 - m^2} \left[ \frac{1}{2} (g_{\mu \lambda} g_{\nu \rho} + g_{\mu \rho} g_{\nu \lambda}) - \frac{1}{3} (g_{\mu \lambda} \gamma_\nu \gamma_\rho + g_{\mu \rho} \gamma_\nu \gamma_\lambda + g_{\nu \lambda} \gamma_\mu \gamma_\rho + g_{\nu \rho} \gamma_\mu \gamma_\lambda) + \frac{1}{10} (g_{\mu \lambda} \gamma_\nu \gamma_\rho + g_{\mu \rho} \gamma_\nu \gamma_\lambda + g_{\nu \lambda} \gamma_\mu \gamma_\rho + g_{\nu \rho} \gamma_\mu \gamma_\lambda) \right]
\]

From Eq. (26), it becomes clear why relation (25) holds without resorting to the decomposition (22) of the propagator. The expansion of \( P_{\mu \nu; \lambda \rho}(p) \) in terms of the projection operators defined in Eqs. (A1)–(A3) reads:

\[
P_{\mu \nu; \lambda \rho}(p) = \left[ \frac{\phi + m}{p^2 - m^2} \mathcal{P}_{3/2} - \frac{4}{5m^2} (\phi + m) \mathcal{P}_{1/2} + \frac{1}{\sqrt{5m}} (\mathcal{P}_{3/2}^2 + \mathcal{P}_{21/2}^2) + \frac{2}{5m^3} (\phi + m)(p^2 - m^2) \mathcal{P}_{11/2} - \frac{1}{5m^3} (\phi + m) \mathcal{P}_{33/2}^2 \right. \\
+ \frac{\sqrt{3}}{5m^4} (\phi + m) \left( \mathcal{P}_{12/2}^2 + \mathcal{P}_{21/2}^2 \right) - \frac{\sqrt{6}}{5m} (p^2 - m^2) (\mathcal{P}_{13/2}^2 + \mathcal{P}_{31/2}^2) - \frac{\sqrt{2}}{5m} \left( \mathcal{P}_{32/2} + \mathcal{P}_{23/2} \right) \left( \mathcal{P}_{\mu \nu; \lambda \rho}(p) \right).
\]

This propagator is a Hermitian operator,

\[
P_{\mu \nu; \lambda \rho}^\dagger(p) = \gamma_0 P_{\lambda \rho; \mu \nu}(p) \gamma_0,
\]

and has the following symmetry properties:

\[
P_{\mu \nu; \lambda \rho}(p) = P_{\nu \mu; \lambda \rho}(p) = P_{\lambda \rho; \mu \nu}(p) = P_{\mu \nu; \rho \lambda}(p).
\]

Moreover, this propagator does not receive contributions from \( \mathcal{P}_{22/2, \mu \nu; \lambda \rho}(p) \) and \( \mathcal{P}_{21/2, \mu \nu; \lambda \rho}(p) \). As a result, it generates consistent couplings from gauge-invariant interaction theories, \( O_{(\mu \nu; \lambda \rho)}^{5/2}(p) O_{(\mu \nu; \lambda \rho)}^{5/2}(p) \), which is fully mediated by the physical spin-5/2 component \( \mathcal{P}_{5/2, \mu \nu; \lambda \rho}(p) \). By combining Eqs. (12) and (21), the consistent interaction structure (25) can be reduced to

\[
O_{(\mu \nu; \lambda \rho)}^{5/2}(p) O_{(\mu \nu; \lambda \rho)}^{5/2}(p) = \frac{\phi + m}{p^2 - m^2} O_{(\mu \nu; \lambda \rho)}^{5/2}(p) O_{(\mu \nu; \lambda \rho)}^{5/2}(p).
\]

which is precisely of the form proposed in Eq. (4). As a result, the unphysical components in the propagator completely decouple from the interaction, which is fully mediated by the physical spin-5/2 component \( \mathcal{P}_{5/2, \mu \nu; \lambda \rho}(p) \). By combining Eqs. (12) and (21), the consistent interaction structure (25) is obtained:

\[
O_{(\mu \nu; \lambda \rho)}^{5/2}(p) O_{(\mu \nu; \lambda \rho)}^{5/2}(p) = \frac{\phi + m}{p^2 - m^2} O_{(\mu \nu; \lambda \rho)}^{5/2}(p) O_{(\mu \nu; \lambda \rho)}^{5/2}(p)
\]

The propagator was obtained from the spin-5/2 projection operator by means of the substitutions (20). These only affect the terms that, at least, are linear in \( p_\mu \), which all vanish upon contraction with the interaction operator since relations (12) hold. As a result, only the physical component of the propagator remains present in Eq. (25).

The above-mentioned method for deriving \( P_{\mu \nu; \lambda \rho}(p) \) raises some issues. As a matter of fact, there is an infinite number of propagators that satisfy conditions (23) and (24) and concurrently lead to consistent interactions. However, it is confirmed by Huang et al., in their paper on the Feynman propagator for a particle with arbitrary spin [9], that expression (21) is indeed the appropriate one for the spin-5/2 propagator apart from a series of noncovariant terms. As emphasized by Weinberg in Ref. [10], the noncovariant terms should be removed from the Feynman propagator to guarantee that the \( S \) matrix remains invariant under proper orthochronous Lorentz transformations. The derivation of the Feynman propagator by Huang et al. does not rely on the expression for the free R-S Lagrangian. Instead, the propagator is derived from the solutions to the R-S Eqs. (1). Therefore, the force that, at least, is linear in \( p_\mu \), which all vanish upon contraction with the interaction operator since relations (12) hold. As a result, only the physical component of the propagator remains present in Eq. (25).

From Eq. (26), it becomes clear why relation (25) holds without resorting to the decomposition (22) of the propagator.

045201-4
In Ref. [11], Shklyar et al. obtained a consistent spin-5/2 interaction by the explicit replacement,
\[ P'_{\mu_1\nu_2\rho}(p) \rightarrow \frac{\gamma^\mu}{p^2 - m^2} T_{\mu_1\nu_2\rho}(p), \tag{28} \]
in the expression for the spin-5/2 interaction structure. They use the following expression for \( P'_{\mu_1\nu_2\rho}(p) \):
\[ P'_{\mu_1\nu_2\rho}(p) = \frac{\gamma^\mu}{p^2 - m^2} \left( \frac{1}{2} (S_{\mu_1\nu_1} S_{\nu_2\rho} + S_{\mu_2} S_{\nu_3}) - \frac{1}{3} S_{\mu_1\nu_1} S_{\nu_2\rho} \right) + \frac{1}{10} (S_{\mu_1} S_{\nu_1} S_{\rho} + S_{\mu_2} S_{\nu_2} S_{\rho}) + \frac{1}{5} (S_{\mu_3} S_{\rho} + S_{\mu_4} S_{\rho}), \tag{29} \]
with
\[ S_{\mu\nu}(p) = -S_{\mu\nu} + \frac{1}{m^2} p_{\mu} p_{\nu}, \]
\[ S_{\mu\nu}(p) = \gamma^\nu S_{\mu\nu}(p), \]
\[ = -\gamma_\mu + \frac{\gamma^\mu}{m^2} p_{\mu}. \tag{30} \]
Note that \( P'_{\mu_1\nu_2\rho}(p) \) does not coincide with \( P_{\mu_1\nu_2\rho}(p) \) of Eq. (21). In Ref. [11], Shklyar et al. assume that a uR-S\( S_{5/2} \) gauge-invariant interaction leads to the substitution (28) in the spin-5/2 interaction structure. However, they do not prove this statement. Furthermore, \( P'_{\mu_1\nu_2\rho}(p) \) is not a spin-5/2 propagator, it is a regular spin-5/2 projection operator that is multiplied with \((p - m)^{-1}\). By regular, we mean that the singular \( p^2 \) and \( p^{-1} \) factors of the spin-5/2 projection operator are replaced with the factors \( m^2 \) and \( m^{-2} \), respectively.

**B. Massive fermion fields with arbitrary spin**

1. The general consistent interaction structure

In the previous section, it was demonstrated how consistent interaction structures can be constructed for off-shell spin-5/2 fields. These results will now be generalized for off-shell spin-\( s \) fermions with \( s = n + 1/2 \) and \( n \in \mathbb{N}^+ \).

The generalized interaction operator is defined as
\[ G^{n+1/2}_{(\mu_1\ldots\mu_n,\nu_1\ldots\nu_n)(\lambda_1\ldots\lambda_n)}(\partial) = \frac{1}{(n!)^2} \sum_{P(p)} \sum_{P(\lambda)} O^{3/2}_{(\mu_1,\nu_1,\lambda_1)}(\partial) \cdots O^{3/2}_{(\mu_n,\nu_n,\lambda_n)}(\partial). \tag{31} \]

Note that
\[ G^{n+1/2}_{(\mu_1\ldots\mu_n,\nu_1\ldots\nu_n)(\lambda_1\ldots\lambda_n)}(\partial) = \frac{1}{(n!)^3} \sum_{P(p)} \sum_{P(\lambda)} \sum_{P(\lambda')} O^{3/2}_{(\mu_1,\nu_1,\lambda_1)}(\partial) \cdots O^{3/2}_{(\mu_n,\nu_n,\lambda_n)}(\partial) = 0, \tag{32} \]
since this operator is symmetric under \( \mu_i \leftrightarrow \nu_j \) and \( O^{3/2}_{(\mu,\nu,\lambda)} = -O^{3/2}_{(\nu,\mu,\lambda)} \). The associated gauge-invariant field for the spin-(\( n + 1/2 \)) theory is given by
\[ G_{\mu_1\ldots\mu_n,\nu_1\ldots\nu_n} = O^{n+1/2}_{(\mu_1\ldots\mu_n,\nu_1\ldots\nu_n)(\lambda_1\ldots\lambda_n)}(\partial) \psi^{\lambda_1\ldots\lambda_n}, \tag{33} \]
where \( \psi_{\mu_1\ldots\mu_n} \) represents the spin-(\( n + 1/2 \)) R-S field. By considering the expression for \( O^{n+1/2}_{(\mu_1\ldots\mu_n,\nu_1\ldots\nu_n)(\lambda_1\ldots\lambda_n)}(\partial) \) of Eq. (31) and the total symmetry of \( \psi_{\mu_1\ldots\mu_n} \) in its Lorentz indices, the expression for \( G_{\mu_1\ldots\mu_n,\nu_1\ldots\nu_n} \) in Eq. (33) is reduced to
\[ G_{\mu_1\ldots\mu_n,\nu_1\ldots\nu_n} = \frac{1}{n!} \sum_{P(\mu)} O^{3/2}_{(\mu_1,\nu_1,\lambda_1)}(\partial) \cdots O^{3/2}_{(\mu_n,\nu_n,\lambda_n)}(\partial) \psi^{\lambda_1\ldots\lambda_n}. \tag{34} \]
This expression for \( G_{\mu_1\ldots\mu_n,\nu_1\ldots\nu_n} \) can be reformulated as
\[ G_{\mu_1\ldots\mu_n,\nu_1\ldots\nu_n} = \sum_{P(\mu)} \sum_{P(\nu)} \sum_{P(\lambda)} G^\mu_{\nu_1,\lambda_1} \cdots G^\nu_{\lambda_n,\mu_n} \chi_{\mu_1\ldots\mu_n}, \tag{35} \]
with
\[ G^\mu = \frac{i^n}{n! (n - k)!} \psi^{\lambda_1\ldots\lambda_n} \chi_{\mu_1\ldots\mu_n}. \tag{36} \]

The field \( G_{\mu_1\ldots\mu_n,\nu_1\ldots\nu_n} \) is totally symmetric in its \( \mu_j \) and \( \nu_j \) indices and has the following property:
\[ G_{\mu_1\ldots\mu_n,\nu_1\ldots\nu_n} = (-1)^n G_{\nu_1\ldots\nu_n,\mu_1\ldots\mu_n}. \tag{37} \]

Furthermore, it is invariant under the \( uR-S_{n+1/2} \) gauge,
\[ \psi_{\mu_1\ldots\mu_n} \rightarrow \psi_{\mu_1\ldots\mu_n} + \frac{i}{n(n - 1)!} \sum_{P(\mu)} \delta_{\mu_1} \chi_{\mu_2\ldots\mu_n}, \tag{38} \]
with \( \chi_{\mu_1\ldots\mu_n} \) as an arbitrary totally symmetric space-time-dependent rank-(\( n - 1 \)) tensor-spinor field. The invariance of \( G_{\mu_1\ldots\mu_n,\nu_1\ldots\nu_n} \) under the \( uR-S_{n+1/2} \) gauge (38) is assured by the following properties of the interaction operator:
\[ \delta^{\lambda_1} G^{n+1/2}_{(\mu_1\ldots\mu_n,\nu_1\ldots\nu_n)(\lambda_1\ldots\lambda_n)}(\partial) = \frac{1}{(n!)^3} \sum_{P(\mu)} \sum_{P(\nu)} \sum_{P(\lambda)} O^{3/2}_{(\mu_1,\nu_1,\lambda_1)}(\partial) \cdots O^{3/2}_{(\mu_n,\nu_n,\lambda_n)}(\partial) = 0, \tag{39} \]
where \( k \) runs from 1 to \( n \). The interaction theory,
\[ L = \tilde{G}_{\mu_1\ldots\mu_n,\nu_1\ldots\nu_n} T^{\mu_1\ldots\mu_n,\nu_1\ldots\nu_n} \hat{T}_{\mu_1\ldots\mu_n,\nu_1\ldots\nu_n} G^{\mu_1\ldots\mu_n,\nu_1\ldots\nu_n}, \tag{40} \]
couples the gauge-invariant field \( G_{\mu_1\ldots\mu_n,\nu_1\ldots\nu_n} \) to the external source \( T_{\mu_1\ldots\mu_n,\nu_1\ldots\nu_n} \), generates transverse interaction vertices, i.e.,
\[ p_{\mu} \Gamma^{\mu-\nu}_{\mu_{\nu_1}\ldots\mu_{\nu_n}} = 0. \tag{41} \]
where \( k \) runs from 1 to \( n \). \( p_{\mu} \) represents the four-momentum of \( \psi_{\mu_1\ldots\mu_n} \), and \( \Gamma^{\mu-\nu}_{\mu_{\nu_1}\ldots\mu_{\nu_n}} \) represents the interaction vertex derived from \( O^{n+1/2}_{(\mu_1\ldots\mu_n,\nu_1\ldots\nu_n)(\partial)} T^{\mu_1\ldots\mu_n,\nu_1\ldots\nu_n} \).

The next step consists of defining the spin-(\( n + 1/2 \)) projection operators. The general expressions for the spin-projection operators for bosons and fermions were first derived by Behrends and Fronsdal in Ref. [12]. The spin-(\( n + 1/2 \)) projection operator is defined as
\[ p_{\mu} O^{n+1/2}_{(\mu_1,\ldots,\nu_n)}(p) = \frac{n + 1}{2n + 3} \gamma^\mu \frac{1}{2n + 3} \psi_{\mu_1\ldots\mu_n,\nu_1\ldots\nu_n}(p) \psi^\nu. \tag{42} \]
and depends on the spin-(n + 1) projection operator. The expression for the spin-n projection operator reads

\[ P_{n}^{\mu_{1}...\mu_{n};v_{n}}(p) = \frac{1}{n!^2} \sum_{P(\mu) P(v)} \sum_{k=0}^{k_{\text{max}}} A_{k}^{n} P_{\mu_{1}\mu_{2}} P_{v_{1}v_{2}} \cdots P_{\mu_{2k-1}\mu_{2k}} P_{v_{2k-1}v_{2k}} \prod_{i=2k+1}^{n} P_{\mu_{i};v_{i}} \]  

with

\[ k_{\text{max}} = \begin{cases} \frac{n}{2}, & n \text{ even,} \\ \frac{n-1}{2}, & n \text{ odd,} \end{cases} \]  

The coefficients \( A_{k}^{n} \) and \( B_{k}^{n} \) read

\[ A_{k}^{n} = \frac{1}{(-2)^{k}} \frac{1}{n!^2} \frac{(2n - 2k + 1)!!}{(2n + 1)!!} \]  

and

\[ B_{k}^{n} = -\frac{1}{(-2)^{k}} \frac{1}{n!^2} \frac{(2n - 2k + 1)!!}{(2n + 1)!!} \]  

The spin-(n + 1/2) projection operator is totally symmetric in its \( \mu_{i} \) indices as well as in its \( v_{j} \) indices and satisfies the R-S constraints,

\[ \gamma^{\mu_{1}} P_{n+1/2}^{\mu_{1}...\mu_{n};v_{n}}(p) = P_{n+1/2}^{\mu_{1}...\mu_{n};v_{n}}(p) \gamma_{v_{1}} = 0, \]  

\[ p^{\mu_{1}} P_{n+1/2}^{\mu_{1}...\mu_{n};v_{n}}(p) = P_{n+1/2}^{\mu_{1}...\mu_{n};v_{n}}(p) p^{v_{1}} = 0. \]  

The general expression for the spin-(n + 1/2) propagator, which was derived by Huang et al. in Ref. [9], consists of a covariant part and a noncovariant part. The covariant part of the propagator is given as

\[ P_{\mu_{1}...\mu_{n};v_{1}...v_{n}}(p) = \frac{\not{p} + m}{p^{2} - m^{2}} P_{n+1/2}^{\mu_{1}...\mu_{n};v_{1}...v_{n}}(p). \]  

The on-shell spin-projection operator \( \tilde{P}_{n+1/2}^{\mu_{1}...\mu_{n};v_{1}...v_{n}}(p) \) is obtained from the off-shell spin-projection operator and \( P_{\mu\nu} \),

\[ P_{\mu\nu} = g_{\mu\nu} - \frac{1}{p^{2}} p_{\mu} p_{\nu}. \]  

The coefficients \( A_{k}^{n} \) are given as

\[ A_{k}^{n} = \frac{1}{(-2)^{k}} \frac{1}{k!} \frac{(2n - 2k - 1)!!}{(2n + 1)!!}. \]  

However, expression (42), for the spin-(n + 1/2) projection operator, can be elaborated further by explicitly carrying out the contractions with the Dirac matrices. This leads to a more convenient expression for the projection operator. Through a series of tedious calculations, which is the subject of Appendix B, the definition of the spin-(n + 1/2) projection operator is reformulated as

\[ P_{n+1/2}^{\mu_{1}...\mu_{n};v_{n}}(p) \]  

through the substitutions,

\[ P_{\mu\nu}(p) = g_{\mu\nu} - \frac{1}{p^{2}} p_{\mu} p_{\nu} \]

\[ \not{p}(p) \not{p}_{\nu}(p) \]

and

\[ P_{\mu}(p) P_{\nu}(p) = \gamma_{\mu} \gamma_{\nu} + \not{p}(\gamma_{\mu} p_{\nu} - \gamma_{\nu} p_{\mu}) - \frac{1}{p^{2}} p_{\mu} p_{\nu} \]

\[ \gamma_{\mu} \gamma_{\nu} + \not{p}(\gamma_{\mu} p_{\nu} - \gamma_{\nu} p_{\mu}) - \frac{1}{m^{2}} p_{\mu} p_{\nu}. \]  

These are equivalent to the substitutions (20) carried out for the spin-5/2 theory. Obviously, the noncovariant part of the propagator should be ignored to preserve the Lorentz invariance of the transition amplitude as required by the special theory of relativity.

The consistency of gauge-invariant interactions, which are described by the interaction Lagrangian (40), can now be proven. As becomes clear from substitutions (52), the spin-(n + 1/2) propagator \( P_{\mu_{1}...\mu_{n};v_{1}...v_{n}}(p) \) differs from the spin-(n + 1/2) projection operator \( P_{n+1/2}^{\mu_{1}...\mu_{n};v_{1}...v_{n}}(p) \) in the momentum-dependent terms. However, by considering the properties of Eq. (39), the momentum-dependent terms of the propagator drop out from the interaction structure. As a consequence, the general interaction structure is invariant under substitutions of the type (52), and the propagator can be replaced by

\[ P_{\mu_{1}...\mu_{n};v_{1}...v_{n}}(p) \rightarrow \frac{\not{p} + m}{p^{2} - m^{2}} P_{n+1/2}^{\mu_{1}...\mu_{n};v_{1}...v_{n}}(p). \]
This proves the consistency of gauge-invariant interactions. The latter property follows directly from the fact that the physical spin-\((n + 1/2)\) component \(\mathcal{P}_{\mu_1\cdots \mu_n}\) of \(\Psi_{\mu_1\cdots \mu_n}\) mediates the interaction.

The expression for the most general consistent interaction structure is reduced to
\[
O_{\mu_1\cdots \mu_n,\nu_1\cdots \nu_n,\eta_1\cdots \eta_n}(p) = \sum_{\nu_1,\cdots,\nu_n} \sum_{\eta_1,\cdots,\eta_n} G^{\nu_1\cdots \nu_n,\eta_1\cdots \eta_n}(p) \left( \mathcal{P}_{\mu_1\cdots \mu_n} \right) \left( \mathcal{P}_{\nu_1\cdots \nu_n,\eta_1\cdots \eta_n} \right)
\]

owing to relations (39). From Eq. (54), it can be concluded that the power of the momentum dependence of the consistent interaction structure rises with the spin of the R-S field. This is a direct consequence of the gauge invariance of the interaction. Indeed, the spin-specific momentum dependence of the consistent interaction structure is provided by the two interaction operators of Eq. (54), and the interaction operator consists of products of \(n\) four-momenta as can be derived from the definition of \(O^{\nu_1\cdots \nu_n,\eta_1\cdots \eta_n}(p)\) in Eq. (31).

2. Consistent couplings for the \((\phi \psi \psi^* \mu_1\cdots \mu_n)\) and \((A_\mu \phi \psi^* \mu_1\cdots \mu_n)\) theories

Consistent interaction theories for off-shell spin-(\(n + 1/2\)) fields can be constructed from the gauge-invariant field \(G_{\mu_1\cdots \mu_n,\nu_1\cdots \nu_n}\), which is defined as
\[
G_{\mu_1\cdots \mu_n,\nu_1\cdots \nu_n} = \sum_{P(\mu)} \sum_{P(\nu)} \sum_{P(\eta)} G_{\mu_1\cdots \mu_n} \partial_{\nu_1} \cdots \partial_{\nu_n} \times \partial_{\eta_1} \cdots \partial_{\eta_n}
\]

From \(G_{\mu_1\cdots \mu_n,\nu_1\cdots \nu_n}\), a much more convenient gauge-invariant field can be derived by considering the fact that \(G_{\mu_1\cdots \mu_n,\nu_1\cdots \nu_n}\) possesses twice as many Lorentz indices as the original field \(\psi_{\mu_1\cdots \mu_n}\). This field is defined as
\[
\Psi_{\mu_1\cdots \mu_n} = \gamma_{\nu_1} \cdots \gamma_{\nu_n} G_{\mu_1\cdots \mu_n,\nu_1\cdots \nu_n} = \sum_{P(\mu)} \sum_{P(\nu)} \sum_{P(\eta)} G_{\mu_1\cdots \mu_n} \partial_{\nu_1} \cdots \partial_{\nu_n} \times \partial_{\eta_1} \cdots \partial_{\eta_n}
\]

and shares the properties of \(\psi_{\mu_1\cdots \mu_n}\). Indeed, it has the same number of Lorentz indices, it is a totally symmetric field, and it obeys the R-S constraints,

\[
\partial^\mu \psi_{\mu_1\cdots \mu_n} = 0, \quad \gamma^\mu \psi_{\mu_1\cdots \mu_n} = 0.
\]

That is, the field combinations in Eqs. (57) result in a zero transition amplitude, as will be clarified shortly. The corresponding interaction operator for the field \(\psi_{\mu_1\cdots \mu_n}\) reads
\[
\mathcal{O}^{(n+1/2)}_{(\mu_1\cdots \mu_n,\nu_1\cdots \nu_n)}(\partial) = \gamma_{\nu_1} \cdots \gamma_{\nu_n} \mathcal{O}^{(n+1/2)}_{(\mu_1\cdots \mu_n,\nu_1\cdots \nu_n)}(\partial)
\]

\[
= \frac{1}{n!} \sum_{\mu_1,\cdots,\mu_n} \mathcal{O}^{(3/2)}_{(\mu_1,\cdots,\mu_n)}(\partial) \cdots \mathcal{O}^{(3/2)}_{(\mu_n)}(\partial),
\]

\[
\mathcal{O}^{(3/2)}_{(\mu_1,\cdots,\mu_n)}(\partial) = \gamma^\nu \mathcal{O}^{(3/2)}_{(\mu_1,\cdots,\mu_n)}(\partial) = i(\partial_\nu \gamma_\mu - \partial_\mu \gamma_\nu).
\]

Indeed, only the term \(-\beta^\nu \mathcal{O}^{(n+1/2)}_{(\mu_1\cdots \mu_n,\nu_1\cdots \nu_n)}(\partial)\) of the interaction operator, which corresponds to the term \(-i(\beta^\nu \mathcal{O}^{(n+1/2)}_{(\mu_1\cdots \mu_n,\nu_1\cdots \nu_n)}(\partial)\) of \(\psi_{\mu_1\cdots \mu_n}\), contributes to the interaction structure. All other terms of the interaction operator contain at least one \(\gamma_\mu\) and, subsequently, vanish because of the first of properties (50). Since the interaction structure associated with \(\psi_{\mu_1\cdots \mu_n}\) is proportional to the spin-(\(n + 1/2\)) projection operator \(\mathcal{P}_{\mu_1\cdots \mu_n,\nu_1\cdots \nu_n}(p)\), relations (57) follow immediately from properties (50). Equation (60) is just how a consistent local interaction structure would be constructed in an intuitive way. It is proportional to the spin-(\(n + 1/2\)) projection operator, which ensures the consistency of the interaction, and the nonlocalities of the latter are exactly canceled through the \(\beta^{2n}\) factor.

To construct consistent couplings for the \((\phi \psi \psi^* \mu_1\cdots \mu_n)\) and \((A_\mu \phi \psi^* \mu_1\cdots \mu_n)\) theories, the spin-3/2 theory is considered first, since this is the most simple and, hence, the most studied R-S theory. Popular choices for the \((\phi \psi \psi^* \mu_1\cdots \mu_n)\) and \((A_\mu \phi \psi^* \mu_1\cdots \mu_n)\) couplings read [13]

\[
\mathcal{L}^{(\phi \psi \psi^*)} = \frac{i g_\psi}{m_\phi} \bar{\psi} \gamma^\nu \Theta_{\mu \nu}(z_0) \Gamma \psi \beta^\nu + \text{H.c.},
\]

\[
\mathcal{L}^{(A_\mu \phi \psi^*)} = \frac{ig_\psi}{m_\phi} \bar{\psi} \gamma^\nu A_\mu \gamma^\nu \Theta_{\mu \nu}(z_0) \Gamma \psi + \text{H.c.},
\]
and

\[ L_{\Lambda_\mu}^{(1)} = \left( \frac{i g_1}{2 m_\phi} \right) \psi_{\mu} \theta_{\nu} (z_1) \Gamma_{\nu} \frac{F_{\mu \nu}}{H.c.}, \]

\[ L_{\Lambda_\mu}^{(2)} = - \frac{g_2}{4 m_\phi} \psi_{\mu} \theta_{\nu} (z_2) \Gamma_\nu \frac{F_{\mu \nu}}{H.c.}, \quad (62) \]

\[ L_{\Lambda_\mu}^{(3)} = - \frac{g_3}{4 m_\phi} \psi_{\mu} \theta_{\nu} (z_3) \Gamma_\nu \frac{F_{\mu \nu}}{H.c.}. \quad (63) \]

Here, the \( g_i \)'s are coupling constants, the \( z_i \)'s are so-called off-shell parameters, \( \theta_{\mu}(z) = g_{\mu \nu} - (z + \frac{1}{2}) g_{\mu \nu} \) is the off-shell tensor, and \( F_{\mu \nu} = \partial_{\mu} A_{\nu} - \partial_{\nu} A_{\mu} \). Furthermore, \( \Gamma = 1 \) if the parities of the outgoing state and the incoming state are equal, and \( \Gamma = -1 \) in the opposite situation. The Lagrangians of Eqs. \( (61) \) and \( (62) \) are inconsistent since they involve off-shell interactions that are mediated by the spin-1/2 component of \( \psi_\mu \). This comes as no surprise since these couplings are not gauge invariant. However, the inconsistent off-shell interactions can be turned into consistent interactions by means of the substitution,

\[ \theta_{\mu}(z) \psi \to \frac{1}{m} \Psi_\mu, \quad (63) \]

where \( m \) represents the mass of \( \phi \) or twice the mass of \( \psi \). The new consistent \((\phi \psi_\mu^*)^+ \) and \((A_\mu \psi_\mu)^+ \) couplings read

\[ L_{\phi \psi_\mu^* +} = \frac{i g_0}{m_\phi} \psi_{\mu} \gamma_{\nu} \frac{F_{\mu \nu}}{H.c.}, \quad (64) \]

and

\[ L_{\Lambda_\mu}^{(1)} = \frac{i g_1}{4 m_\phi} \psi_{\mu} \gamma_{\nu} \frac{F_{\mu \nu}}{H.c.}, \]

\[ L_{\Lambda_\mu}^{(2)} = - \frac{g_2}{8 m_\phi} \psi_{\mu} \gamma_{\nu} \frac{F_{\mu \nu}}{H.c.}, \quad (65) \]

\[ L_{\Lambda_\mu}^{(3)} = - \frac{g_3}{8 m_\phi} \psi_{\mu} \gamma_{\nu} \frac{F_{\mu \nu}}{H.c.}. \]

The consistency of these interactions is guaranteed by the explicitly gauge-invariant field \( \Psi_\mu = \gamma_\mu \psi \) (67a). Note that the derivative, which acts on \( \phi \) in Lagrangian \( (64) \), cannot be replaced by a Dirac matrix because of property \( (57a) \). The interaction Lagrangian with the derivative, which acts on \( \psi \), i.e.,

\[ L_{\phi \psi_\mu^* +} = \frac{i g_0}{m_\phi} \psi_{\mu} \gamma_{\nu} \frac{F_{\mu \nu}}{H.c.}, \quad (66) \]

is equivalent to Eq. \( (64) \), aside from a minus sign, as seen from partial integration and property \( (57b) \).

The consistent interaction Lagrangians for the spin-3/2 theory, i.e., Eqs. \( (64) \) and \( (65) \), can be generalized for the spin-(\( n + 1/2 \)) theory. The consistent \((\phi \psi_\mu^* \psi_\mu^*)^+ \) and \((A_\mu \psi_\mu)^* \psi_\mu^+ \) couplings read

\[ L_{\phi \psi_\mu^* \psi_\mu^* +} = \frac{i g_0}{m_\phi} \psi_{\mu} \gamma_{\nu} \frac{F_{\mu \nu}}{H.c.}, \quad (67) \]

\[ L_{\Lambda_\mu}^{(1)} = \frac{i g_1}{2 m_\phi} \psi_{\mu} \gamma_{\nu} \frac{F_{\mu \nu}}{H.c.}, \]

\[ L_{\Lambda_\mu}^{(2)} = - \frac{g_2}{4 m_\phi} \psi_{\mu} \gamma_{\nu} \frac{F_{\mu \nu}}{H.c.}, \quad (68) \]

Indeed, the joining \( (n - 1) \) Lorentz indices of \( \psi_\mu^+ \), as compared to \( \psi_\mu^+ \), can only be contracted by derivatives that do not act on \( \psi_\mu^+ \) since properties \( (57) \) hold.

## III. CONSISTENT INTERACTIONS IN HADRON PHYSICS

The nucleon has various excited states, which are commonly dubbed nucleon resonances. They are identified with their different masses, spins, and decay widths, which reflect the specific internal structure of the resonance. The quantitative information on the excited nucleon states is gathered by the Particle Data Group (PDG) from various partial-wave analyses, which aims at describing pion- and photon-induced meson production processes [14]. Alternatively, these processes can be described by isobar models. An extensive overview of the various partial-wave and isobar models is found in Ref. [15]. To describe nucleon excitation processes in a consistent way, isobar models require a consistent high-spin interaction theory. Such a theory was developed in Sec. II B2. The following sections illustrate how this interaction theory can be implemented in the study of processes that are of key importance in hadron physics. To this end, the \( K^+ \Lambda \) photoproduction process from the proton is selected

\[ \gamma p \rightarrow K^+ \Lambda. \quad (69) \]

It is worth stressing that all discussions of the following sections apply equally well to other hadronic processes that involve off-shell high-spin interactions.

### A. Inconsistency of standard hadronic form factors

The threshold energy \( W_0 \) for \( K^+ \Lambda \) production is given by [14]

\[ W_0 = m_{K^+} + m_\Lambda \approx 1610 \text{ MeV}. \quad (70) \]

In an effective-field framework, the \( p(\gamma, K^+)\Lambda \) reaction is modeled with hadrons as the basic degrees of freedom, i.e., the hadrons are represented by effective quantum fields. The expression for the differential \( p(\gamma, K^+)\Lambda \) cross section in the center-of-mass frame is given by [16]

\[ \frac{d\sigma}{d\Omega_K} = \frac{1}{64\pi^2} \frac{1}{W^2} E_{\gamma}^{lab} \sum_{\lambda, \lambda_p, \lambda_L} |M_{\lambda, \lambda_p, \lambda_L}|^2. \quad (71) \]

Here, \( W \) is the invariant mass, \( E_{\gamma}^{lab} \) is the photon energy in the laboratory frame, \( \theta_K \) is the three-momentum, and \( \theta_K \) is the scattering angle of the kaon in the center-of-mass frame. Furthermore, \( \lambda, \lambda_p, \) and \( \lambda_L \) are the photon, proton, and hyperon polarizations. The notation \( \sum_{\lambda, \lambda_p, \lambda_L} \) denotes appropriate summing and/or averaging over the polarizations.
of initial- and final-state particles. Finally, $M_{\lambda_{p}, \lambda_{h}: \lambda_{h}}$ is the total transition amplitude. Its squared absolute value is calculated as

$$|M_{\lambda_{p}, \lambda_{h}, \lambda_{h}}|^2 = |\nu_{\lambda_{h}} T_{\mu}^{\lambda_{h}} u_{\lambda_{h}|\lambda_{h}}|^2,$$

(72)

where $\nu_{\lambda_{h}}$ and $u_{\lambda_{h}}$ are as the proton and hyperon spinors, $e_{\mu}$ as the polarization four-vector of the photon, and $T_{\mu}$ as the truncated interaction current.

Figure 1 depicts the tree-level Feynman diagram for the resonant $s$-channel contribution to the $p(\gamma, K^+)\Lambda$ reaction. In this channel, the photon excites the proton to form a nucleon resonance, which is labeled $N^*$. In the $N^*$'s rest frame, the spin of $N^*$ can be determined by the photon-proton relative orbital angular momentum. The nucleon resonance subsequently decays into a $K^+$ and a $\Lambda$. To account for the finite lifetime of $N^*$, the following substitution in the expression for the $N^*$ propagator is required:

$$\frac{p_R + m_R}{p_R^2 - m_R^2} \rightarrow \frac{p_R + m_R}{p_R^2 - m_R^2 + i m_R \Gamma_R}.$$

(73)

In the tree-level approximation of Fig. 1, the propagator remains undressed. As a consequence, the decay width of the unstable particle, i.e., the resonance, is not generated dynamically. Then, the finite lifetime of the resonance can be implemented by means of the substitution of Eq. (73).

From expression (71), the unpolarized total cross section

$$\sigma(W) = \int \frac{d \Omega_K}{64 \pi^2} \frac{1}{W^2} \frac{1}{E_{\gamma}^{1/2}} \sum_{\lambda_{p},\lambda_{h},\lambda_{h}} |M_{\lambda_{p}, \lambda_{h}, \lambda_{h}}|^2,$$

(74)

can be calculated. In the presented calculations, the coupling constants of Eqs. (67) and (68) are chosen to be equal, i.e., $g_0 = g_1 = g_2 = g$. The coupling constant $g$ is determined from the requirement that $\sigma_{\max} = 0.10 \, \mu b$, which is the typical order of magnitude for the reaction $\gamma p \rightarrow K^+ \Lambda$. In Fig. 2, $\sigma$ is plotted for three artificial resonances with $m_R = 1700 \, \text{MeV}$, $\Gamma_R = 50 \, \text{MeV}$, and spins $J_R^p = 1/2^+, 3/2^+, 5/2^+$. The coupling constant $g$ for each of the three resonances is denoted by $g_{1/2}$, $g_{3/2}$, and $g_{5/2}$. The explicit expressions for the spin-1/2+, the spin-3/2+, and the spin-5/2+ truncated currents are given by

$$T_{1/2^+} = \left( g_0 \gamma \right) \left( \frac{p_R + m_R}{p_R^2 - m_R^2 + i m_R \Gamma_R} \right) \times \left[ i e g_1 \left( k_{\mu} - m_R \gamma_{\mu} \right) \right].$$

(75)

$$T_{3/2^+} = \left( i g_0 \gamma \right) \left( \frac{p_R + m_R}{p_R^2 - m_R^2 + i m_R \Gamma_R} \right) \times \left[ i e g_1 \left( k_{\mu} - m_R \gamma_{\mu} \right) \right] + \frac{i e g_2}{8 m_p^3} \gamma_3 \left( (k_{\mu})^{1/2} s_{\mu} - k_{\nu} \gamma_{\nu} \right).$$

(76)

$$T_{5/2^+} = \left( i g_0 \gamma \right) \left( \frac{p_R + m_R}{p_R^2 - m_R^2 + i m_R \Gamma_R} \right) \times \left[ i e g_1 \left( k_{\mu} - m_R \gamma_{\mu} \right) \right] + \frac{i e g_2}{32 m_p^3} \gamma_5 \left( (k_{\mu})^{1/2} s_{\mu} - k_{\nu} \gamma_{\nu} \right).$$

(77)

and the corresponding cross sections are denoted as $\sigma_{1/2^+}$, $\sigma_{3/2^+}$, and $\sigma_{5/2^+}$. In the above expressions, $e$ represents the charge of the proton, $k_{\mu}$, $p_{\mu}$, $p_{K^+ \Lambda}$, and $p_{R, \mu} = k_{\mu} + p_{\mu}$ represent the four-momenta of the photon, the proton, the kaon, and $N^*$. Furthermore, $m_p$ and $m_{K^+}$ are the masses of the proton and the kaon. Note that $p_R^2 = W^2$. The expression for $T_{1/2^+}$ was obtained from Ref. [17]. The expressions for $T_{3/2^+}$ and $T_{5/2^+}$ were derived from the consistent interaction Lagrangians (67) and (68) and the consistent interaction structure (60). Since the equations of motion for the real photon field are...
given by
\[ \partial_\mu F^{\mu\nu} = 0, \] (78)
the truncated currents \( J^{3/2}_\mu \) and \( J^{5/2}_\mu \) do not receive contributions from the third Lagrangian of Eq. (68).

By inspecting Fig. 2, it is observed that \( \sigma_{1/2} \) decreases asymptotically with \( W \), whereas, \( \sigma_{3/2} \) and \( \sigma_{5/2} \) grow indefinitely with \( W \). The higher the spin of the resonance, the faster \( \sigma \) rises with \( W \). This clearly is an unphysical and an unacceptable behavior. To remedy this, one commonly introduces a hadronic form factor, which cuts the transition amplitude \( \mathcal{M}_{1\lambda_0^\gamma\lambda_0} \) beyond a certain energy scale. Hadronic form factors that are commonly used in the literature are of the dipole form [18]
\[ F_d(s; m_R, \Lambda_R) = \frac{\Lambda_R^4}{(s - m_R^2)^2 + \Lambda_R^4}, \] (79)
or the Gaussian form [19]
\[ F_G(s; m_R, \Lambda_R) = \exp \left( -\frac{(s - m_R^2)^2}{\Lambda_R^4} \right), \] (80)
with \( s = W^2 \) and \( \Lambda_R \) as the cutoff energy.

For the remainder of this discussion, the following resonant \( s \)-channel contribution to the \( p(\gamma, K^+)\Lambda \) reaction will be investigated in detail,
\[ \gamma p \rightarrow N(1680) F_{15} \rightarrow K^+ \Lambda. \] (81)
The nucleon resonance \( N(1680) F_{15} \) is an established \( J^P = 5/2^+ \) resonance with a four-star rating in the Review of Particle Physics of the PDG [14]. It has a mass \( m_R = 1685 \) MeV and a decay width \( \Gamma_R = 130 \) MeV. The computed cross section that uses a Gaussian form factor to cut off the transition amplitude at high energies is denoted as \( \sigma_G \). The value of the cutoff energy is fixed at a typical value of \( \Lambda_R = 1500 \) MeV. The result of the calculation of \( \sigma_G \) is shown in Fig. 3(a). A seemingly resonant structure is observed. This structure, however, is not associated with the resonant structure of the \( N(1680) F_{15} \). Indeed, \( \sigma_G \) has \( W_{\text{max}} \approx 2250 \) MeV and \( \text{FWHM} \approx 450 \) MeV, with \( W_{\text{max}} \) as the invariant mass that corresponds to the transition amplitude at high energies.

Clearly, the computed energy dependence of \( \sigma_G \) displays little resemblance to the expected behavior of a resonance with \( m_R = 1685 \) MeV and \( \Gamma_R = 130 \) MeV. Figure 3(b), which provides a closer look at \( \sigma_G \) in the threshold-energy region, reveals that any sign of a resonant structure at \( W \approx m_R \) is missing.

The observed energy dependence of \( \sigma_G \), which can be conceived as unphysical, is generated by the combination of the opposite high-energy behavior of \( \sigma \) and \( F_G \). In the high-energy limit, \( \sigma \) rises with the energy as observed in Fig. 2. This feature is characteristic for off-shell high-spin interactions. On the other hand, \( F_G \) decreases for growing \( W > m_R \). For a particular value of the invariant mass, denoted by \( W_{\text{max}} \), the decrease in \( F_G \) becomes strong enough so as to prevent \( \sigma_G \) from growing indefinitely. As a result, the maximum value of \( \sigma_G \) is reached at \( W_{\text{max}} \), and an artificial structure is created. The fact that the resonant structure at \( W \approx m_R \) is not observed in the computed energy dependence of \( \sigma_G \) can be attributed to the relatively large decay width of the \( N(1680) F_{15} \) in combination with the fast increase in \( \sigma \) with growing \( W \).

Clearly, the computed cross section \( \sigma_G \) of Fig. 3(a) lacks any obvious physical meaning. Indeed, the resonant structure at \( W \approx m_R \) is erased, and an unphysical bump dominates \( \sigma_G \) for \( m_R \lesssim W \lesssim 3000 \) MeV. A clear-cut remedy consists in cutting off the physics at smaller energies, i.e., lowering \( \Lambda_R \). Figure 4(a) illustrates the energy dependence of \( \sigma_G \) for a range of cutoff energies. Indeed, it is observed that lowering \( \Lambda_R \) results in a mere shift in the unphysical bump toward the threshold energy \( W_0 \). The peak position and width of the bump in the energy dependence of \( \sigma_G \) appear to be a function of \( \Lambda_R \). The unphysical bump persists in the threshold-energy region, reveals that any sign of a resonant structure at \( W \approx m_R \) is missing.
FIG. 4. (Color online) The energy dependence of the γp → N(1680)F15 → K⁺Λ cross section for various values of the cut-off energy of the Gaussian form factor. In (a), the real decay width of the N(1680)F15 was used, i.e., ΓR = 130 MeV, and g = 2.4, 3.3, 4.2, 5.3 for ΛR = 1250, 1000, 750, 500 MeV. In (b), the decay width of the N(1680)F15 was set to ΓR = 20 MeV and g = 2.6.

It is important to stress that, with the dipole form factor of Eq. (79), things get even worse. Indeed, the dipole form factor is restricted to a pure spin-5/2 amplitude: 

$$\psi_{\mu\nu} = \frac{g^2}{m^4} D_{\mu\nu;\lambda\rho}(\theta) \psi_{\lambda\rho},$$  

with m as an arbitrary mass. The gauge-invariant field $\psi_{\mu\nu}$ is restricted to a pure spin-5/2 component. This restriction is indispensable since the spin-5/2 propagator of Ref. [6] does not generate consistent couplings from interaction theories that are only required to be invariant under the $uR$-$S_{1/2}$ (6) as clarified in Sec. II A3. The gauge-invariant field $\psi_{\mu\nu}$ gives rise to the following truncated current for the tree-level $p(\gamma, K^+)\Lambda$ amplitude:

$$T'_\mu = \left( -\frac{p_R^2}{m_K^2} \right) T_\mu - \frac{p_R^2}{4m^2} T'_\mu,$$

with $T_\mu$ defined in Eq. (77). Since it features additional powers of W, the corresponding cross section grows even stronger with W in the high-energy limit than by applying the consistent interaction theory of Sec. II B2. It is clear that its unphysical behavior is even more problematic.

B. The multi-dipole-Gauss form factor

In Sec. III A, it was pointed out that the unphysical behavior of $\sigma_G$ is caused by the divergent high-energy behavior of $\sigma$ in the tree-level approximation. This feature is characteristic for consistent high-spin interactions. To restore the physical resonance peak, the high-energy behavior of $\sigma$ needs to be regulated. The angular dependence of $\sigma$, which reflects the quantum numbers of the exchanged particles, should be left unaltered by such an operation.

In the expression for the consistent interaction structure (60), the prefactor $(p_R^2)^{n_R} = s^{n_R}$, with $n_R = J_R - \frac{1}{2}$, combined with the $2n_R$ four-momenta that are to be contracted with the spin-$J_R$ projection operator, give rise to a factor $s^{2n_R} = (s^2)^{J_R-1/2}$ for $s \gg m_R^2$. It is exactly this factor that causes the unphysical behavior of $\sigma_G$. To resolve these problems, the $(s^2)^{J_R-1/2}$ factor needs to be included in the denominator of the hadronic form factor. This can be achieved by multiplying $J_R - \frac{1}{2}$ dipole form factors (79) with the Gaussian form factor (80). The following explicit form for the modified hadronic form factor is suggested:

$$F_{mG}(s; m_R, \Lambda_R, \Gamma_R, J_R) = \left( \frac{m_R^2 \frac{1}{2} (\Lambda_R)_{J_R}}{(s - m_R^2) + \frac{1}{4} m_R^2 (\Lambda_R)_{J_R}} \right)^{J_R-1/2} \times \exp \left( -\frac{(s - m_R^2)^2}{\Lambda_R^2} \right),$$

and is dubbed a multi-dipole-Gauss form factor. To preserve the interpretation of the decay width of the resonance as the FWHM of the resonance peak, a modified decay width $\Gamma_R$ is required. The explicit expression for the modified decay width depends on the spin of the resonance and reads

$$\Gamma_R(J_R) = \frac{\Gamma_R}{\sqrt{2^{[J_R/2]} - 1}}.\quad (85)$$

The details of the derivation of the expression for $\Gamma_R(J_R)$ have been diverted to Appendix C. The above choice for $F_{mG}$ is inspired by the expression for the squared absolute value of the propagator denominator, i.e.,

$$(p_R^2 - m_R^2 + im_R\bar{\Gamma}_R)^{-1} \left( p_R^2 - m_R^2 - im_R\bar{\Gamma}_R \right)^{-1} = \left[ (s - m_R^2)^2 + m_R^2 \bar{\Gamma}_R^2 \right]^{-1},$$

where $p_R^2 = s$ has been substituted. In this way, the multi-dipole-Gauss form factor raises the multiplicity of the propagator pole at the resonance mass.

Figure 5(a) compares a multi-dipole-Gauss form factor with $\Lambda_R = 1500$ MeV to a Gaussian form factor with the same FWHM. Despite the fact that the two form factors shown in Fig. 5(a) appear similar, their effect on $\sigma$ is vastly different. This is illustrated in Fig. 5(b), which depicts the computed cross sections that adopt both form factors. As explained before, the energy dependence of $\sigma_G$ should be interpreted as artificial. The peak position and width of the observed structure
in $\sigma_G$ are determined by the value of the cutoff energy. The multi-dipole-Gauss form factor has a larger impact on the high-energy behavior of $\sigma$ and prevents the formation of an artificial bump. The form factor $F_{mG}$ augments the effect of the $N(1680)$ $F_{15}$'s propagator, and this makes sure that, in the computed $\sigma_{mG}$, the resonance peak occurs at $W \approx m_R$. Yet, it appears as though the mass of the $N(1680)$ $F_{15}$ is shifted by approximately 100 MeV. This mass shift is a threshold effect and is caused by the fact that $m_R - \gamma_R \approx W_0$ and $\sigma(W_0) = 0$. The mass shift decreases with increasing resonance mass and decreasing resonance decay width.

In Fig. 6, the cross sections of Fig. 4 are replotted by employing a multi-dipole-Gauss form factor. The minor shift in the resonance peak in Fig. 6(a) does not have the same origin as the artificial bump of Fig. 4(a). Here, the shift is caused by the comparable magnitudes of $\Lambda_R$ and $\Gamma_R$. As a consequence, the resonance peak gets increasingly narrowed by the form factor, and this results in a reduction in the mass shift, which was explained in the previous paragraph. In Fig. 4(b), the decay width of the $N(1680)$ $F_{15}$ was artificially lowered to $\gamma_R = 20$ MeV. Here, it is apparent that the energy dependence of $\sigma_{mG}$ is indeed the same for all cutoff energies. Figure 4(b) also confirms the fact that the mass shift decreases with decreasing decay width: The mass shift amounts to approximately 3.5 MeV.

**IV. CONCLUSIONS**

In this paper, a theory of consistent interactions for massive high-spin fermions was developed. It was proven that gauge symmetry was the necessary and sufficient condition to assure the consistency of high-spin interactions. From this gauge symmetry, the most general consistent interaction structure was constructed for off-shell high-spin fermions. In addition, consistent couplings for the $(\phi \psi \psi^* \psi \mu_1 \cdots \mu_a)$ and $(A_R \psi \psi^* \psi \mu_1 \cdots \mu_a)$ theories were derived.

It turns out that the power of the momentum dependence of consistent couplings rises with the spin of the R-S field. This gives rise to unphysical behavior in the computed tree-level cross sections if the reaction is cut off by a standard hadronic form factor. A persuasive solution was proposed in terms of an alternative phenomenological hadronic form factor, namely, the multi-dipole-Gauss form factor. We deem that this form factor, in conjunction with the consistent interaction Lagrangians developed in Sec. II B2, provides a proper framework to implement the exchange of high-spin resonances in hadrodynamical analyses.

APPENDIX A: THE PROJECTION OPERATORS FOR THE SPIN-5/2 THEORY

The projection operators for the spin-5/2 theory read [6]

\[ P_{\mu
u\lambda\rho}^{5/2}(p) = \frac{1}{2} (P_{\mu\lambda} P_{\nu\rho} + P_{\mu\rho} P_{\nu\lambda}) - \frac{1}{5} P_{\mu\lambda}, P_{\nu\rho} - \frac{1}{10} (P_{\mu\lambda} P_{\nu\rho} + P_{\mu\rho} P_{\nu\lambda}), \]

(\text{A1})

\[ P_{11,\mu
u\lambda\rho}(p) = \frac{1}{2} (P_{\mu\lambda} Q_{\nu\rho} + P_{\mu\rho} Q_{\nu\lambda}) - \frac{1}{5} P_{\mu\lambda}, Q_{\nu\rho} - \frac{1}{10} (P_{\mu\lambda} Q_{\nu\rho} + P_{\mu\rho} Q_{\nu\lambda}), \]

(\text{A2})

\[ P_{22,\mu
u\lambda\rho}(p) = \frac{1}{10} (P_{\mu\lambda} P_{\nu\rho} + P_{\mu\rho} P_{\nu\lambda} - \frac{1}{15} P_{\mu\lambda}, P_{\nu\rho} - \frac{2}{15} P_{\mu\lambda}, P_{\nu\rho}, \]

\[ P_{33,\mu
u\lambda\rho}(p) = \frac{1}{6p^2} R_{\mu\lambda} R_{\nu\rho}, \]

(\text{A3})

with

\[ P_{\mu\nu}(p) = 8_{\mu
u} - \frac{1}{p^2} (p_{\mu} p_{\nu}), \quad P_{\mu
u}(p) = \gamma^\nu P_{\mu\nu}(p) - \frac{1}{p^2} (p_{\mu} p_{\nu}), \quad Q_{\mu\nu}(p) = \frac{1}{p^2} (p_{\mu} p_{\nu}), \]

(\text{A4})

The projection operators project the spin-5/2 field \( \psi_{\mu\nu} \) onto the (physical) spin-5/2 component and the (unphysical) spin-3/2 and spin-1/2 components, respectively. The following orthogonality relations apply to these operators [7]:

\[ g^{\sigma\prime} g^{\tau\prime} P_{i\ell,\mu\nu\sigma\tau}(p) P_{k\ell,\sigma\prime\tau\prime}(p) = \delta_{i\prime}^{\prime} \delta_{k\prime}^{\prime} \delta_{\ell\prime}^{\prime} P_{i\prime,\mu\nu\sigma\tau}(p). \]

(\text{A5})

APPENDIX B: THE SPIN-(n + 1/2) PROJECTION OPERATOR

The \( k \)th term in expression (42) for the spin-(\( n + 1/2 \)) projection operator reads

\[ \frac{\eta^{n+1}}{2^{n+1}(n+1)!} \gamma^{\mu_1} \left( \sum_{P(\mu)} \sum_{P(\nu)} A_k^{n+1} P_{\mu_1\mu_2} P_{\nu_1\nu_2} \cdots P_{\mu_2}\cdots\mu_{n+1} P_{\nu_2}\cdots\nu_{n+1} \Gamma_{n+1}^{n+1}(\mu_1\cdots\nu_{n+1}) \right) \gamma^{\nu_1}. \]

(\text{B1})

The braces indicate how many times the relevant factor can be transformed into itself by applying permutations of the Lorentz indices, which are contained in the double sum. From now on, the factor \( \frac{n+1}{2^{n+1}(n+1)!} \) and the double sum are dropped for reasons of simplicity. By explicitly carrying out the contractions with the Dirac matrices, five different terms are obtained, namely,

\[ A_k^{n+1} P_{\mu_1\mu_2} P_{\nu_1\nu_2} \cdots P_{\mu_2}\cdots\mu_{n+1} P_{\nu_2}\cdots\nu_{n+1} \Gamma_{n+1}^{n+1}(\mu_1\cdots\nu_{n+1}) \]

(\text{B2})

\[ A_k^{n+1} P_{\mu_1\mu_2} P_{\nu_1\nu_2} \cdots P_{\mu_2}\cdots\mu_{n+1} P_{\nu_2}\cdots\nu_{n+1} \Gamma_{n+1}^{n+1}(\mu_1\cdots\nu_{n+1}) \]

(\text{B3})

045201-13
Note that only expressions (B5) and (B6) have a $k = 0$ term. All of these terms have to be multiplied with a factor that accounts for the modified number of permutations that can be performed to transform the relevant term into itself. These factors read

$$\frac{4^k k!^2 (n - 2k + 1)!}{4^{k-1} (k-1)!^2 (n - 2k + 1)!} = 4k^2, \quad (B7)$$

$$\frac{4^k k!^2 (n - 2k + 1)!}{4^k k! (k-1)! (n - 2k)!} = k(n - 2k + 1), \quad (B8)$$

$$\frac{4^k k!^2 (n - 2k + 1)!}{4^k k! (k-1)! (n - 2k)!} = k(n - 2k + 1), \quad (B9)$$

$$\frac{4^k k!^2 (n - 2k + 1)!}{4^k k! (n - 2k)!} = n - 2k + 1, \quad (B10)$$

$$\frac{4^k k!^2 (n - 2k + 1)!}{4^k k! (n - 2k)!} = (n - 2k + 1)(n - 2k), \quad (B11)$$

By renaming the Lorentz indices and by using the following properties:

$$\gamma^\mu \gamma^\nu = -\gamma^\nu \gamma^\mu + 2\gamma^\mu, \quad (B12)$$

expressions (B2)–(B6) can be transformed into

$$(B2) \to 4(k + 1)^2 A_{k+1}^n P_{\mu_1 \mu_2} P_{\nu_1 \nu_2} \cdots P_{\mu_2 \mu_{k+1}} P_{\nu_2 \nu_{k+1}} \prod_{i=2k+2}^n P_{\mu_i \nu_i}, \quad (B13)$$

$$(B3) \to 2k(n - 2k + 1) A_{k}^{n+1} \times P_{\mu_1 \mu_2} P_{\nu_1 \nu_2} \cdots P_{\mu_2 \mu_{k+1}} P_{\nu_2 \nu_{k+1}} \prod_{i=2k+1}^n P_{\mu_i \nu_i}, \quad (B14)$$

$$(B4) \to 2k(n - 2k + 1) A_{k}^{n+1} \times P_{\mu_1 \mu_2} P_{\nu_1 \nu_2} \cdots P_{\mu_{2k-1} \mu_{2k}} P_{\nu_{2k-1} \nu_{2k}} \prod_{i=2k+1}^n P_{\mu_i \nu_i}, \quad (B15)$$

$$(B5) \to 3(n - 2k + 1) A_{k}^{n+1} \times P_{\mu_1 \mu_2} P_{\nu_1 \nu_2} \cdots P_{\mu_{2k-1} \mu_{2k}} P_{\nu_{2k-1} \nu_{2k}} \prod_{i=2k+1}^n P_{\mu_i \nu_i}, \quad (B16)$$

$$\frac{4^k k!^2 (n - 2k + 1)!}{4^k k! (n - 2k)!} = (n - 2k + 1)(n - 2k), \quad (B17)$$

Here, the substitution $k \to k + 1$ was made for expression (B13), and the $k = 0$ term was added for expressions (B14) and (B15) since they are proportional to $k$. In this way, all expressions obtain a $k = 0$ term. Note that the second term of expression (B17) can be rewritten as

$$2(n - 2k + 1)(n - 2k) A_{k}^{n+1} \times P_{\mu_1 \mu_2} P_{\nu_1 \nu_2} \cdots P_{\mu_{2k-1} \mu_{2k}} P_{\nu_{2k-1} \nu_{2k}} \prod_{i=2k+1}^n P_{\mu_i \nu_i}$$

$$= 2(n - 2k + 1)(n - 2k) A_{k}^{n+1} \times P_{\mu_1 \mu_2} P_{\nu_1 \nu_2} \cdots P_{\mu_{2k-1} \mu_{2k}} P_{\nu_{2k-1} \nu_{2k}} \prod_{i=2k+1}^{n-1} P_{\mu_i \nu_i}$$

The transition from expression (B18) to (B19) is valid since both expressions are equal for odd $n$; and for even $n$, the $k = \frac{n}{2}$ term, i.e., the last one, vanishes due to the prefactor $(n - 2k)$. Next, the factor $\frac{n+1}{2n+3} (\frac{1}{n+1})^2$ and the double sum are
introduced again. The sum of expressions (B14)–(B16) and (B19) equals

\[ \sum_{\mu} \sum_{\nu} \sum_{k=0}^{k_{\text{max},1}} A_{\ell}^n \mathcal{P}_{\mu \mu_2} \mathcal{P}_{\nu \nu_2} \]

\[ \cdots \mathcal{P}_{\mu_{2i+1} \mu_{2i+2}} \mathcal{P}_{\nu_{2i+1} \nu_{2i+2}} \sum_{i=2k+2}^{n} \mathcal{P}_{\mu \nu}. \]

(B20)

The coefficients \( A_{\ell}^n \) can be calculated as

\[ A_{\ell}^n = \frac{n + 1}{2n + 3} \left[ 3(n - 2k + 1) + 4k(n - 2k + 1) + 2(n - 2k + 1)(n - 2k) \right] A_{\ell}^{n+1}. \]

(B21)

From the definition of the coefficients \( A_{\ell}^n \), i.e., Eq. (46), the expression for \( A_{\ell}^n \) can be further reduced to

\[ A_{\ell}^n = \frac{(n-2k+1)}{(n+1)!} \left( \frac{1}{(-2)^k} \frac{(n+1)!}{(2n-2k+1)!} \right). \]

(B22)

For even values of \( n \), one has \( k_{\text{max},1} = \frac{n-1}{2} \). For odd values of \( n \), this becomes \( k_{\text{max},1} = \frac{n+1}{2} \).

Finally, the sum of expression (B13) and the first term of expression (B17) equal

\[ \sum_{\mu} \sum_{\nu} \sum_{k=0}^{k_{\text{max},2}} B_{\ell}^n \mathcal{P}_{\mu \mu_2} \mathcal{P}_{\nu \nu_2} \]

\[ \cdots \mathcal{P}_{\mu_{2i+1} \mu_{2i+2}} \mathcal{P}_{\nu_{2i+1} \nu_{2i+2}} \sum_{i=2k+2}^{n} \mathcal{P}_{\mu \nu}. \]

(B23)

The coefficients \( B_{\ell}^n \) are then given by

\[ B_{\ell}^n = \frac{n + 1}{2n + 3} \left[ 4(k+1)^2 A_{\ell}^{n+1} - (n - 2k + 1)(n - 2k) A_{\ell}^{n+1} \right]. \]

(B24)

For even values of \( n \), one has \( k_{\text{max},1} = \frac{n+2}{2} \). For odd values of \( n \), this becomes \( k_{\text{max},1} = \frac{n-1}{2} \).

APPENDIX C: THE MODIFIED DECAY WIDTH FOR THE MULTI-DIPOLE-GAUCS FORM FACTOR

The expression for the total cross section of Eq. (74) is proportional to the following factor:

\[ \sigma(s) \propto \left[ (s - m_R^2)^2 + m_R^2 \bar{r}_R^2 \right]^{-2J_R}. \]

(C1)

which stems from the squared multi-dipole-Gauss form factor and the squared spin-\( J_R \) propagator denominator. The values of \( s \), which correspond to the half maximum of this factor are the solutions to the equation,

\[ \left[ (s - m_R^2)^2 + m_R^2 \bar{r}_R^2 \right]^{2J_R} = 2(m_R^2 \bar{r}_R^2)^{2J_R}. \]

(C2)

These are found as

\[ s_{\pm} = m_R^2 \left( 1 \pm \frac{\bar{r}_R}{m_R} \sqrt{2J_R} \right). \]

(C3)

The FWHM is then calculated as

\[ \text{(FWHM)}_R = \sqrt{s_+} - \sqrt{s_-}. \]

(C4)

If \( \bar{\Gamma}_R \) is defined as

\[ \bar{\Gamma}_R(J_R) = \frac{\Gamma_R}{2^{1/2J_R} - 1}, \]

(C5)

then

\[ \text{(FWHM)}_R \approx \bar{\Gamma}_R, \]

(C6)

for \( \Gamma_R \ll m_R \), which is the desired result.
